Project OPR-J377-KR2-15  
Locality: Approaches to Breton Sound, LA  
June 2015  
S/V *Blake*  
**David Evans and Associates, Inc.**  
Chief of Party: Jonathan L. Dasler, PE, PLS, CH

## **INTRODUCTION**

This report applies to the OPR-J377-KR2-15 project area that includes surveys H12737, H12738, H12739, H12740 and H12847 located in the approaches to Breton Sound, Louisiana. Surveys H12737, H12738, H12739 and H12740 meet requirements defined in the *Statement of Work* (April 3, 2015) and *Hydrographic Survey Project Instructions* (April 3, 2015). An additional survey, H12847, was issued after data acquisition began on the first four surveys and performed under OPR-J377-KR2-15 Mod 1, as specified in the *Statement of Work* (July 30, 2015) and *Hydrographic Survey Project Instructions* (August 7, 2015). Surveys H12737, H12738, H12739 and H12740 followed the National Ocean Service (NOS) *Hydrographic Surveys Specifications and Deliverables* (HSSD) (April 2014). Survey H12847 followed the 2015 version of the HSSD.

The purpose of this project is to perform modern-day hydrographic surveys of approximately 160 square nautical miles of high traffic area to the east and southeast of Breton Sound, Louisiana for NOS and its nautical charting products.

All references to equipment, software or data acquisition and processing methods were accurate at the time of document preparation. All changes to data acquisition and processing methods will be specifically addressed in the Descriptive Report for each project survey.

## **A. EQUIPMENT**

For this project David Evans and Associates, Inc. (DEA) implemented state-of-the-art data acquisition systems on board the Survey Vessel (S/V) *Blake* in accordance with National Oceanic and Atmospheric Administration (NOAA) standards and modern remote sensing techniques. Operational systems used to acquire survey data and redundant systems that provided confidence checks are described in detail in this section and are listed in Table 1.

## A1. Survey Vessel

The S/V *Blake*, owned and operated by DEA (Figure 1), was the survey vessel for the project. The S/V *Blake*, is a 92-ton United States Coast Guard (USCG) Subchapter T inspected vessel, Official Number 1256966, and Hull Number 213. She is an 83-foot aluminum catamaran with 27-foot beam and a draft of 4.5 feet. The vessel is equipped with wave-piercing bows, Tier-3 diesel engines, twin 55-kilowatt generators, centerline moon pool with hydraulic multibeam strut, stern mounted A-frame, bow mounted knuckle boom crane, climate controlled equipment and server closet, two data acquisition stations and two data processing stations. The S/V *Blake* supports a hydrographic crew of six and is supported by four ship crew for 24-hour survey operations.

**Figure 1. S/V *Blake***

## A2. Side Scan Sonar Systems

Side scan sonar imagery was only acquired for survey H12847 with an Edgetech 4200-HF (300/600 kHz) dual frequency side scan sonar. The sonar was operated in high-frequency, high-speed mode at 600 kHz for data collected at 50-meter and 75-meter range scales. As stated in the 2015 HSSD, side scan sonar was acquired to achieve 100 percent coverage.

Side scan sonar imagery was logged as eXtended Triton Format (XTF) (16 bit, 2048 pixels/channel) in Triton Isis SS-Logger. In addition to the imagery, vessel heading, pitch, roll, position, towfish depth and altitude, and computed towfish position from layback calculations were also recorded to the XTF.

The side scan sonar towfish was either deployed from the bow or stern of the vessel. For each configuration, the horizontal offset of the tow point relative to the vessel reference point was entered into Hypack. The tow point position calculated in Hypack was sent to SS-Logger and

used as the raw towfish position. When using the cable out method, an LCI-90 cable payout interface was used to measure cable out during stern tow and a fixed cable out was used for bow tow. The cable out, along with the measured tow point height above the waterline and towfish depth was used by SS-Logger to compute layback. When using the fixed layback method, the cable out on the bow or stern was set at a fixed distance and the horizontal distance from the tow point to the towfish was measured. This horizontal layback was entered into SS-Logger as a positive value as the towfish was always aft of the tow point.

To confirm adequate target resolution at the outer limits of the selected range, confidence checks were conducted on a daily basis during acquisition and noted in the acquisition logs. In deteriorating conditions, confidence checks were performed more frequently to confirm detection of features at the outer range limits.

### **A3. Multibeam System**

The S/V *Blake* was equipped with a Reson SeaBat 7125-SV2 SPU G5 dual frequency multibeam sonar capable of operating at 200 kHz or 400 kHz, and integrated AML Micro SV Xchange sound velocity sensor. The multibeam was deployed with a center lift-mount through a moon pool. For all surveys the sonar was operated with FP 4 in Equi-Angle Beam mode using real-time roll stabilization. Surveys H12737, H12738, H12739, and H12740 used a sonar frequency of 200 kHz. Under typical operation the sonar was configured to acquire a 120-degree swath of 512 beams. In some cases, when sonar coverage was required around platforms, the full 140-degree swath used in order to avoid creating survey holidays under platforms. For survey H12847 the sonar was operated at 200 kHz and 400 kHz using a 120-degree swath of either 256 or 512 beams.

All multibeam data were acquired with either the 200 kHz SV2 bracket or 400 kHz SV2 bracket (PN85160026C02) selected in the hardware configuration. Multibeam data were output using the 7006 datagram, which references all soundings with respect to the 7125 sonar reference point. Range adjustments were made during acquisition as dictated by changes in water depth. HYPACK HYSWEEP was used to acquire multibeam data in HYSWEEP HSX file format and snippets in 7K file format.

### **A4. Position, Heading and Motion Reference Systems**

The S/V *Blake* was outfitted with a POS/MV 320 version 4 with GPS and inertial reference system, which was used to measure attitude, heading, heave, and position. The system was comprised of an Inertial Motion Unit (IMU), dual frequency (L1/L2) GPS antennas, and a data processor.

A Trimble SPS351 DGPS acquired corrections from the USCG beacon located at either Eglin Air Force Base, Florida (295 kHz) or English Turn, Louisiana (293 kHz); and provided differential corrections to the POS/MV. In addition, a Trimble SPS351 DGPS receiver was used as a redundant positioning system to provide secondary DGPS corrected positions for quality control purposes.

Positions from all systems were displayed in real-time using Hypack and continuously compared during survey operations.

A weekly position comparison between the primary and secondary positioning system was observed and documented while the vessel was either secured in port, or within the extents of the survey area. Logged position data were extracted from the Hypack RAW file and entered into an Excel file for comparison. Position check reports can be found in Separate I *Acquisition and Processing Logs* of each survey's Descriptive Report.

Position, timing, heading and motion data were output to the Hypack acquisition system using the POS/MV real-time Ethernet option at 25 Hz.

The POS/MV provided time synchronization of sonar instruments and data acquisition computers using a combination of outputs. The Reson processors and Hypack acquisition computers were provided a Pulse Per Second (PPS) and National Marine Electronics Association (NMEA) Global Positioning System Timing Message (ZDA) to achieve synchronization with the POS/MV. The Isis SS-Logger acquisition computer synchronized its time using the proprietary Trimble Universal Time Coordinated (UTC) message provided by the POS/MV. All messages contained time strings that enabled the acquisition computers and sonars to synchronize to the time contained within the message. Time offsets between the instruments and computers, relative to the times contained in POS/MV network packets, were typically sub-millisecond.

Using the Ethernet logging controls, the POS/MV was configured to log all of the raw observable groups needed to post process the real-time sensor data. The POS/MV logged 64 megabyte .000 files, which resulted in multiple files created per day. The TrueHeave™ data group was also logged to these files.

## **A5. Sound Speed Measurement Systems**

Sound speed sensors were calibrated prior to the start of acquisition. Factory calibration results are included in Appendix IV *Sound Speed Sensor Report* of this report.

An AML Micro X SV sensor mounted on the Reson 7125 sonar head was input into the Reson 7-P processor and speeds from the sensor were used in real-time during acquisition for beam forming on the 7125's flat array. A Rolls Royce MVP 30-350 equipped with AML Oceanographic Micro SV&P sensors was used as the primary sound speed sensor for the S/V *Blake*. A Seabird SBE 19-03 SeaCAT was used as the secondary sound speed sensor. All sound speed calculations from the Sea-Bird Conductivity, Temperature, and Depth (CTD) profiler used the Chen-Millero equation. These profiles were used solely for confidence checks with the primary sensor.

## **A6. Acquisition and Processing System**

The acquisition stations were custom-installed and integrated on the S/V *Blake* by DEA and consisted of a HYPACK HYSWEEP multibeam acquisition and navigation computer, an MVP computer and a computer for digital logs and general administration. The S/V *Blake* had an

additional Triton Isis SS-Logger side scan sonar data acquisition computer and two processing computers.

Data collected from the S/V *Blake* were logged locally on each acquisition computer and continuously backed up to a QNAP network attached storage (NAS) device. A secondary QNAP NAS was used to perform backups of the primary QNAP. At each vessel port call, acquisition and processing data from the primary QNAP were transferred to the Gulfport, MS and Vancouver, WA offices via two external USB 3.0 hard drives.

The software and version numbers used throughout the survey are listed in Table 2.

## **A7. Survey Methodology**

### **A7.a Mobilization**

Mobilization, final sensor installation, and squat testing of the S/V *Blake* occurred at Gulfport Small Craft Harbor in Gulfport, MS on November 14, 2014 (DN 318), prior to the start of NOAA project OPR-J311-KR-14. Vessel offsets and associated measurement uncertainties for the S/V *Blake* were calculated from a vessel offset survey performed at Geo Shipyard in New Iberia, LA on September 23-24, 2014 (DN 266-267). There have been no changes to the hardware offsets since the initial vessel offset survey. All survey points were positioned using a terrestrial land survey total station from a minimum of two locations, which allowed a position uncertainty to be determined. Vessel offsets and uncertainties were used in the HIPS HVF. System calibrations and a start of project patch test were run over a deep water feature adjacent to the project area on April 15, 2015 (DN 105).

### **A7.b Survey Coverage**

Complete coverage multibeam with backscatter was acquired for surveys H12737, H12738, H12739 and H12740 using requirements set in the 2014 HSSD. The multibeam coverage was monitored during acquisition using a HYPACK HYSWEEP matrix with various resolutions (2, 4 and 8-meter), dependent on the water depth. Matrix settings were adjusted to account for swath width, vessel draft and tides. In places where coverage was insufficient or the vessel had to maneuver to avoid obstructions around offshore platforms in the survey area, targets were marked in HYPACK Survey in order to subsequently fill gaps. Soon after collection, coverage was evaluated in the field by computing CARIS Combined Uncertainty and Bathymetry Estimate (CUBE) surfaces. Fill lines were created over gaps in the CUBE surface or over significant features that required more coverage to obtain a least depth. Raw multibeam data was restricted to a swath of 120-degree within the Reson acquisition software to obtain sufficient data density was achieved. In shallower waters (less than 20 meters), where the proximity to baring features increased the risk to the vessel, additional fill lines were planned with a 140-degree swath. To ensure the quality of the data collected at the outer beams for the extended swath additional crosslines and patch test were conducted with this swath angle setting applied.

The survey requirement for H12847 was 100 percent side scan sonar coverage with concurrent set line spacing MBES with backscatter up to the survey boundary or the inshore limit, which ever came first. The project instructions for this survey area required the use of the 2015 HSSD which implemented new specifications for side scan acquisition using only 100 percent coverage. The side scan sonar was operated at 50-meter and 75-meter range with 50 and 80-meter survey line spacing. In areas where a charted feature was found not to exist, a second 100-percent coverage was acquired in order to meet feature disproval requirements. Additional multibeam data was acquired over significant features found in either the multibeam or side scan data record to obtain a least depth meeting 2015 HSSD complete coverage requirements.

The effective range of the side scan sonar was reduced to 12.5 times the towfish height when height was less than 8 percent of range scale. Additional coverage was acquired to fill any associated holidays created by reducing the range.

The final Project Reference File (PRF) OPR\_J377\_KR2\_15\_PRF.000 was received by DEA on April 22, 2015 by email. The PRF for H12847, OPR\_J377\_KR2\_15\_Mod1\_PRF\_Final.000, was received on August 17, 2015 also by email.

### A7.c Side Scan Sonar Operations

For the duration of the project, the side scan sonar was operated in high-frequency, high-speed mode at 600 kHz and 50-meter and 75-meter range scales.

The EdgeTech 4200 series sonar has a ping rate of 30 Hz at 50-meter range, while operating in the high speed mode. High speed mode makes use of the optional Multi-Pulse (MP) technology, which places two sound pulses in the water at a time rather than the traditional one pulse, and allows for tow speeds upwards of 8 knots. In accordance with the 2015 HSSD, vessel speed was monitored to allow for the acquisition of a minimum of three pings per meter. The side scan was towed from either the bow or stern of the S/V *Blake* during acquisition.

The side scan sonar operator was assigned the task of analyzing the digital sonogram and keeping the towfish height within specification by adjusting cable out. The operator also called out contacts and daily confidence checks, which were entered into the digital acquisition log. When weather or sea conditions degraded side scan sonar imagery, operations were suspended.

### A7.d Multibeam Sonar Operations

The multibeam sonar was operated at different range scales throughout the survey by adjusting the depth range to obtain the best coverage in varying depths of water. Gain and power were adjusted to record a strong bottom return capable of supporting quality depth and backscatter data.

Multibeam investigations occurred over significant features after examining parameters such as coverage, density, feature or contact height, depth and navigational significance.

Table 3 lists the typical 7125 sonar settings for the survey.

**Table 3. Typical Reson 7125 Sonar Settings**

7125 Parameter	Pulse Type: FM	Pulse Type: CW
Operation Depth	>25m	<25m
Range	Variable, depth dependent	Variable, depth dependent
Receive Gain	10-20	10-20
Transmit Power	200-220 dB	200-220 dB
Spreading	30 dB	30 dB
Absorption	110 dB/km	110 dB/km
Ping Rate	20 p/s max	20 p/s max
Pulse Width	1000 $\mu$ s	33 $\mu$ s

### **A7.e Bottom Sampling**

Bottom samples were acquired as specified in the *Hydrographic Survey Project Instructions* in accordance with section 7.1 of the 2014 HSSD. Approximate bottom sample locations were provided by NOAA in the final PRF. The final sampling plan used these locations with some modification of position to assure that they were acquired within the final survey coverage, a suitable distance away from charted pipelines in the survey area.

### **A8. Quality Assurance**

Acquisition and processing methods followed systematic and standardized workflows established by DEA. These systems include, but are not limited to staff training and mentoring, a formalized project management program, record and log keeping standards, software version management, and a multilevel review process.

Multibeam survey data were converted and processed in CARIS HIPS version 8.1. Data processing methodologies followed standard CARIS HIPS workflows for multibeam data.

The default *CUBE Parameters.XML* was replaced with a file issued by NOAA Hydrographic Surveys Technical Directive 2009-2. This updated XML file uses the resolution dependent maximum propagation distance values required in the NOS HSSD.

All side scan contacts that were determined to be significant were investigated with multibeam according to complete coverage specifications. This technique is shown in Figure 2.

**Figure 2. Example of Side Scan Sonar Mosaic Overlaid with Multibeam and Sonar Contact**

## **B. QUALITY CONTROL**

### **B1. Data Acquisition**

#### **B1.a Side Scan Sonar**

Triton Isis SS-Logger acquisition software was used to record side scan sonar data in XTF format. Adjustments to towfish height were made during stern tow data acquisition as necessary and logged in Isis SS-Logger to meet specifications and provide the best image quality possible. Changes to cable out values, sensor settings, offset configurations, data quality and contacts were recorded in the daily acquisition log. Typical windows for monitoring raw sensor information included a waterfall display for the sonar imagery, tow fish motions, cable out and layback, sonar signal voltage display and I/O port monitor. Data were displayed on a 30-inch LCD flat panel

monitor mounted vertically at the acquisition station. The large format display allowed for increased time to analyze online contacts. Contacts were selected in real-time and during post-processing.

To aid in the consistency of contact identification, a table was posted at the side scan acquisition station listing slant range and towfish altitude to determine minimum shadow heights for 0.75-meter contacts at range. Contacts were classified as significant if their estimated height was 0.75 meters or greater. When towing the side scan sonar from the stern of the vessel and using the cable out method for layback calculation, efforts to maintain towfish altitude at 8 to 20 percent of the range was tasked to the side scan operator, who also controlled the winch operation. The operator could view the towfish altitude above the seafloor on the Isis SS-Logger display and adjust cable-out accordingly, to maintain the towfish at the required height. When towing the side scan sonar in shallow regions of the survey area, the towfish was deployed with a fixed cable out with the layback value from the tow point entered into SS-Logger.

The digital cable out value was confirmed by stopping pay out of the tow cable when the 5-meter mark on the cable was at the top of the block sheave. Using this method, the cable-out meter was calibrated during each deployment and continuously during tow operations.

### **B1.b Multibeam**

Multibeam data were acquired in HYPACK HYSWEEP file format (HSX). Adjustments to the sonar, including changes in range, power and gain were made as necessary, in order to acquire the best bathymetric data quality. Additionally, vessel speed was adjusted in accordance with the HSSD to meet the required along track coverage. Typical windows for monitoring raw sensor information included timing synchronization, vessel motion, number of satellites, HDOP and PDOP. Raw attitude and nadir depth were also recorded in HYPACK RAW format, as a supplementary backup. Multibeam snippets were logged in Hypack 7K format.

The HYPACK acquisition station operator monitored and tuned the multibeam sonar, tracked vessel navigation and maintained the digital line log. Operators monitored primary and secondary navigation systems to verify quality position data were acquired at all times.

### **B2. Methodology Used to Maintain Data Integrity**

The acquisition systems and survey protocols were designed with some redundancy to demonstrate that the required accuracy was being achieved during the survey and provide a backup to the primary systems. Data integrity was monitored throughout the survey through system comparisons. Two positioning systems were used to provide real-time monitoring of position data. Position confidence checks, multibeam bar checks, and sound speed comparison checks were conducted regularly to confirm required accuracy was being maintained. Regular comparison checks were performed by comparing profiles from the primary and secondary sound speed sensors that were acquired concurrently. Sound speed profiles were computed for each of the sensors and compared to confirm instrumentation was functioning within required tolerances.

A flow diagram of the data acquisition and processing pipeline is presented in Figure 3. This diagram graphically illustrates the data pipeline and processing workflow from acquisition to delivery. Items in the diagram related to side scan sonar acquisition and processing are only valid for survey H12847.

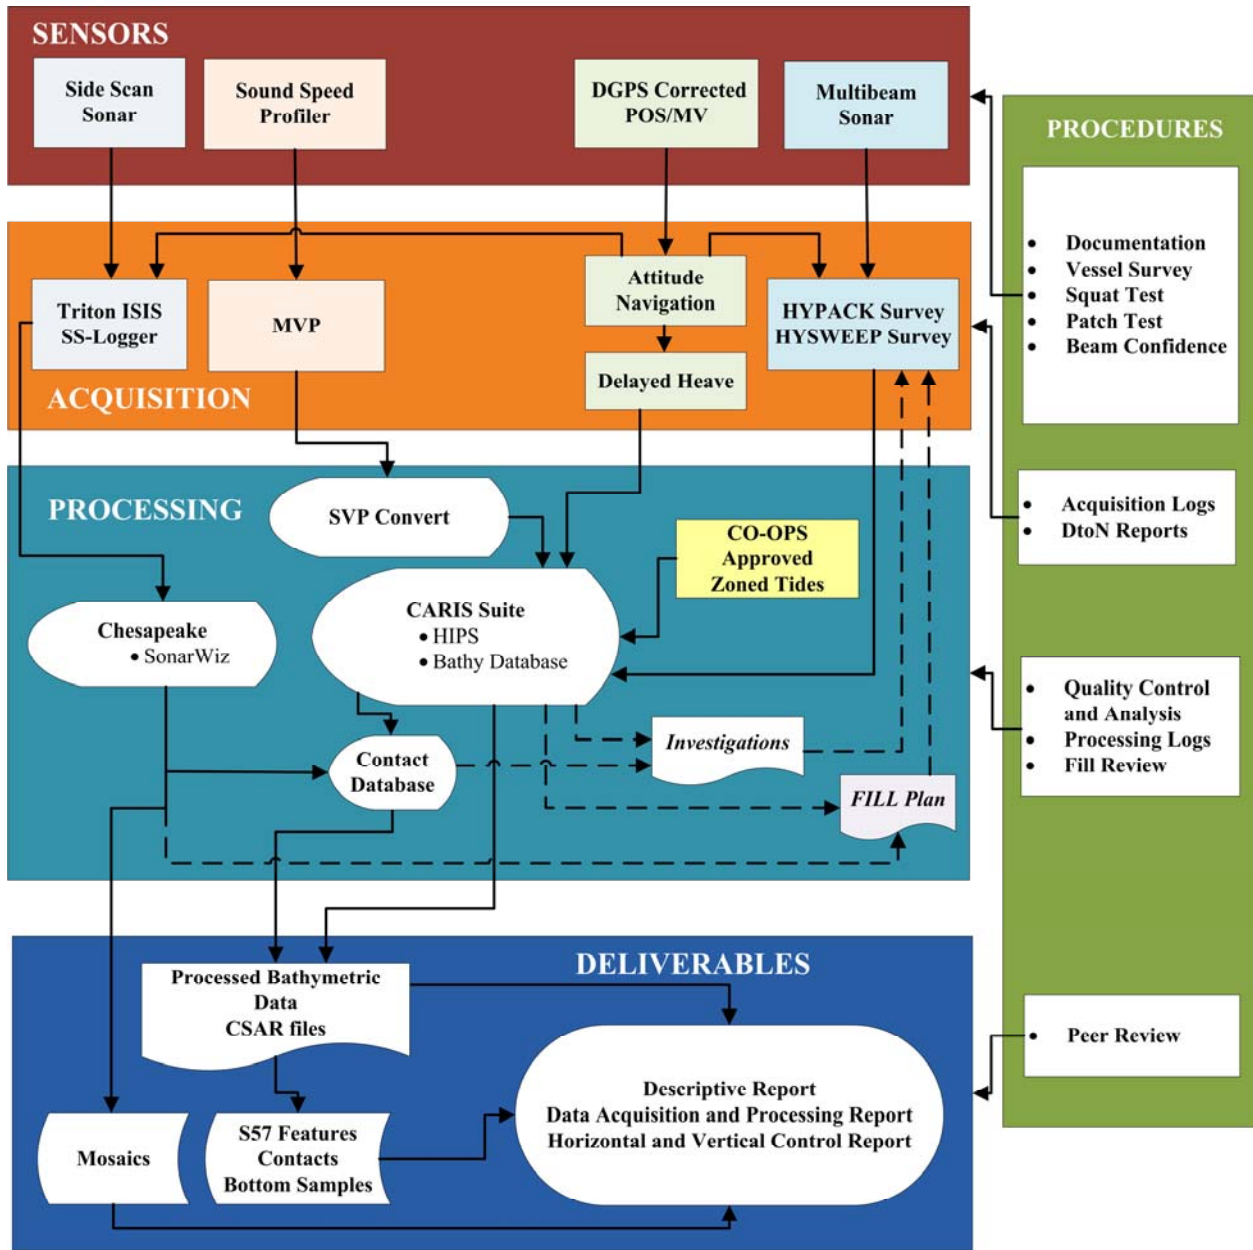

Figure 3. Flowchart of Data Acquisition and Processing Pipeline

## B2.a HIPS Conversion

Multibeam data were converted from RAW and HSX format to CARIS HDCS format using the HYPACK conversion wizard. HIPS ground coordinates (UTM NAD 83 Zone 16N) were selected in the Conversion Wizard dialogue.

When converting multibeam data, the device numbers fields were left blank since there were no duplicate sensors logged in the HSX files. No data were rejected based on quality flags during conversion.

The CARIS output window was reviewed for failures during conversion.

## B2.b Vessel Files

The HIPS vessel files listed in Table 4 contain all offsets and system biases for the survey vessel and its systems, as well as error estimates for latency, sensor offset measurements, attitude and navigation measurements, and draft measurements.

**Table 4. HIPS Vessel Files**

HIPS Vessel File	HIPS Converter	Sonar Type
OPR-J377-KR2-15_MBES_BL_200kHz.hvf	Hypack 8.1.13.0	200kHz Multibeam
OPR-J377-KR2-15_MBES_BL_400kHz.hvf	Hypack 8.1.13.0	400kHz Multibeam

Sensor offsets for the *S/V Blake* were calculated from the vessel survey and dynamic draft values were calculated through the use of post-processed GPS observations. Draft (water line) was measured and entered daily from draft sight tubes located in the port and starboard sponson abeam of the multibeam sonar and vessel reference point. Draft changes relative to the vessel reference point were entered into the multibeam vessel configuration file. These corrections are listed in tabular and graphical format in Appendix I *Vessel Reports*.

Best estimates for Total Propagated Uncertainty (TPU) values were entered into the vessel files based on current knowledge of the TPU/CUBE processing model. The manufacturers' published values were entered into the static sensor accuracy fields. Other values were either calculated or estimated.

The vessel file for 200 kHz operations (OPR-J377-KR2-15\_MBES\_BL\_200kHz.hvf) was configured using the Reson SeaBat 7125 (200 kHz and 256 beams) sonar model. The default sonar model file (devicemodels.xml) included in CARIS HIPS does not include a sonar model for the 7125 running at 200kHz with 512 beams as used during acquisition. This issue did not impact depth uncertainty values since real time sonar uncertainty was logged during acquisition and applied during TPU computation.

Navigation and transducer separation distances from the motion sensor were computed relative to the phase center, vice the top hat, of the motion sensor therefore the vessel file standard deviation offsets will not exactly match the sensor offset values. TPU values for the S/V *Blake* are listed in Table 5.

**Table 5. Hydrographic Vessel File TPU Values**

\*All values given as 1 sigma.

A tide uncertainty consisting of both measurement and zoning errors was provided in the OPR-J377-KR2-15 *Tides and Water Levels Statement of Work*. Tidal uncertainty values for survey H12847 were provided in *OPR-J377-KR2-15 Project Instructions Final Mod 1*. Tide uncertainty values provided by NOAA were at the 95% confidence interval. The total tide uncertainty was entered in the HIPS Tide Value Zoning field during TPU computation at 1-sigma. Sound speed and tide TPU values are listed in Table 6.

**Table 6. TPU Values for Tide and Sound Speed**

<b>Total Propagation Uncertainty Computation in CARIS HIPS</b>	
<b>Tide Values</b>	<b>1-Sigma Uncertainty (m)</b>
Tide Value Measured	0.000
Tide Value Zoning (H12737)	0.128
Tide Value Zoning (H12738)	0.128

Sound Speed Measured	1.00
Surface Sound Speed	0.50

**B2.c Static Draft**

The *S/V Blake* was built with draft dampening tubes in each hull providing a means to monitor vessel static draft. Static draft readings from the port and starboard side draft sight tubes were recorded and averaged every 12 hours during 24-hour operations when sea conditions permitted, and at the start and end of each survey day during 12-hour operations.

The average draft value best approximates the true draft value at the vessel reference point during acquisition due to loading changes from fuel consumption during transit to and from the survey area, at the start and end of each day, or from ballast changes due to water consumption. Ultimately, the daily and 12-hour draft values were used to calculate draft relative the HIPS reference point which was entered into the “Waterline Height” field in the CARIS HVP files.

**B2.d Sound Velocity**

Sound speed profiles were applied to each line using the nearest in distance within time (one hour) option in the CARIS Sound Velocity Profiler (SVP) correct routine. During acquisition, profiles were taken at frequent intervals through the use of the MVP30-350.

**B3. Bathymetric Data Processing**

Multibeam data processing followed the standard HIPS workflow for CUBE editing by primarily using the Hypothesis count layer to direct necessary edits to the multibeam data.

Below is the list of correctors and filters applied to the bathymetric data in HIPS. Several of the steps are interim processes (such as the water levels) and were re-applied as needed. The TPU was re-computed for the multibeam data as needed to reflect changes in the correctors.

- Load delayed heave
- Load zoned tide
- Review attitude editor
- Load attitude/navigation data (when necessary)
- Review navigation editor
- Apply daily concatenated sound speed profiles
  - “Nearest in distance within time 1 hour”
- Merge
  - “Apply delayed heave”
- Compute TPU via values listed in Tables 5 and 6
- Filters soundings with poor quality flags (0)
- Data reviewed and fliers removed in Swath Editor and/or Subset Editor
- Add data to field sheet:
  - “CUBE” weighted surface of appropriate resolution for water depth
    - International Hydrographic Organization (IHO) S-44 Order 1a
    - Density & Local Disambiguation method
    - Advanced configuration using the 2009 NOAA field unit parameters of the appropriate resolution surface
- Review CUBE surface and child layers with tiles with reference surface on

One field sheet was created to correspond to each survey. CUBE surfaces were created over the entire survey area using grid-resolution thresholds and resolution dependent maximum propagation distances for complete coverage surveys as specified in the NOS HSSD.

For survey H12847, CUBE surfaces using complete coverage resolution were created over each multibeam investigation of a significant side scan sonar contact. Survey coverage was specifically reviewed to confirm there were no holidays or data gaps over significant contacts. The HIPS density layer of each multibeam grid was reviewed to confirm that all multibeam investigations over significant features had either a designated sounding from a nadir beam, or the node overlying the least depth had a density of at least five soundings.

All of the multibeam data collected were reviewed in HIPS 3D subset editor with the in-house defined shoal biased reference surface active.

Soundings rejected by quality filters were displayed during editing, and any feature removed by a filter was manually re-accepted. Fliers making the CUBE surface shoaler than expected by more than the allowable International Hydrographic Organization (IHO) Order 1a vertical error were rejected. Designated soundings were used as necessary in order to force the finalized depth surface through reliable shoaler soundings when the difference between the surface and sounding was more than one-half the maximum allowable IHO Order 1a vertical error. In addition, data processors reviewed sounding data and CUBE surfaces for excessive motion artifacts or

systematic biases. All cross lines were manually reviewed for high internal consistency between the datasets and comparison statistics were also computed using the HIPS QC Report tool.

For H12487 contacts exported from the side scan sonar contact data base were displayed in the HIPS background as a Drawing Exchange Format (DXF) file and reviewed for multibeam coverage and significance. Designated soundings were created to denote the least depth of each significant submerged feature.

A large portion of the data processing, QC, and review was performed on the S/V *Blake* during survey acquisition. Dangers to Navigation were reported directly to the DEA project manager via Iridium satellite broadband connection in order to expedite submission to the processing branch. This workflow is shown in Figure 4.

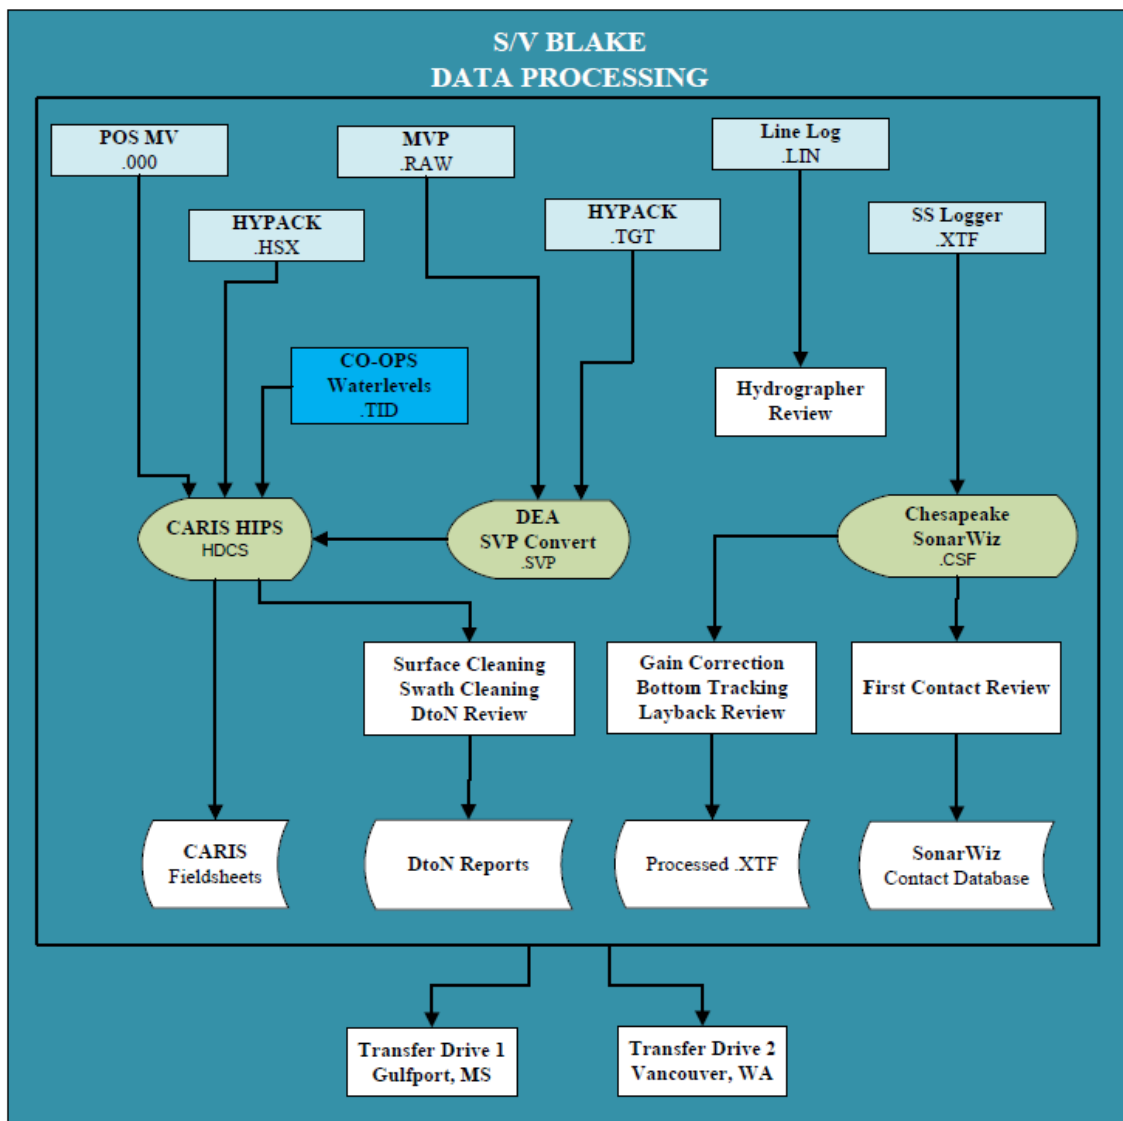

Figure 4. Flowchart of S/V *Blake* Data Processing Pipeline

#### **B4. GPS Post-processing**

Any data found to contain navigation data gaps greater than one second were updated with real-time navigation using the HIPS Load Navigation/Attitude Data tool. The real time navigation data was extracted from the POS/MV .000 files using POSpac MMS software.

Applanix POSpac MMS software was used to create a post-processed navigation solution for all patch test lines. The post-processed solution included new position, height, heading and attitude measurements in Smoothed Best Estimate of Trajectory (SBET) format. The SBET file was applied to the patch test data using the HIPS Load Navigation/Attitude Data tool during patch test processing and analysis.

#### **B5. Final Bathymetric Processing**

Upon the completion of editing multibeam data in HIPS, finalized CUBE grids were generated using the “greater of the two” option for the final uncertainty value. Selected soundings and contours were generated from the surfaces and used for chart comparison purposes, but are not included with the deliverables.

Designated soundings were used as a starting point for S-57 feature creation. Designated soundings that were determined to be obstructions, rocks, wrecks, or other significant features were imported into the S-57 feature files and attributed. S-57 objects were created for all new and incorrectly charted bearing features.

All features were created using the NOAA Profile object catalogue version 5.3.2 which references the NOAA Extended Attributes defined in the NOS HSSD. All mandatory feature attributes have been populated. In addition, the images attribute has been used to provide multibeam and side scan screen shots of features. The feature file also includes meta-object M\_COVR.

#### **B6. Side Scan Processing**

After acquisition on H12487 the XTF files were imported into Chesapeake Technologies Inc. (CTI) SonarWiz and gain corrected. The side scan bottom track was then reviewed and losses of bottom or incorrect bottom track areas were re-digitized. Altitude, tow point offset and cable out were applied. The fish heading was then overwritten with the ship gyro using the Triton ISIS utility MODXTF. The processed lines then underwent two independent reviews to identify significant contacts. In most cases side scan contacts were determined to be significant if the measured height was within 25 centimeters of the significant height requirement to allow for contact measurement error. Also contacts with minimal shadow heights were classified as significant if there were areas deemed to be critical to navigation, or if they appeared to be mounds or other geologic structures, which cast little or no shadow.

Sonar contacts were processed using CTI SonarWiz software. Management of side scan sonar contacts was accomplished by utilizing an in-house utility created for contact tracking and meeting the requirements of the HSSD. The database was maintained and stored in Microsoft

Access using the .MDB file format. Contacts were added into the database on a daily basis upon completion of the side scan review and contact identification. The use of the .MDB format allowed direct geographic display of contacts and spatial queries within ESRI ArcGIS, where contacts were correlated and compared to the chart and other survey data.

Side scan mosaics were created using CTI SonarWiz. Georeferenced mosaics were generated in Tagged Image File Format (TIF) with an associated world file (TWF) at 1 meter.

## **C. CORRECTIONS TO ECHO SOUNDINGS**

### **C1. Static Draft**

A detailed description of the static draft corrections can be found in section B2.c of this report. The daily and 12-hour draft values were used to calculate draft relative the HIPS reference point which was entered into the “Waterline Height” field in the CARIS HVF files.

### **C2. Dynamic Draft**

Dynamic draft values for the both vessels were calculated from a squat test through the use of inertial-aided post-processed Kinematic (PPK) GPS observations utilizing a virtual base from a network of continuously operating reference stations.

A settlement and squat test for the *S/V Blake* using post-processed GPS height observations was performed near Gulfport, MS on November 14, 2014 (DN 318). Results are included in Appendix I *Vessel Reports*.

The settlement and squat values were obtained by computing an average of GPS height values at different ship speeds, measured in knots and revolutions per minute (RPM). Transects were run twice at each RPM interval along opposing headings. With the vessel at rest, static GPS height observations were recorded between each RPM interval, in order to obtain a baseline GPS height value not affected by tide changes during the test. These values were linearly interpolated to determine the baseline GPS height at the time of the dynamic draft measurement. The difference between the GPS height while the vessel was in motion and the interpolated static GPS height was used to calculate the dynamic draft for each transect. An average dynamic draft corrector was then calculated from the average of the two values for each RPM interval. The average speed for each RPM interval and the average dynamic draft corrector were entered into the HIPS vessel file. Uncertainty estimates for dynamic draft were calculated by taking the average of the standard deviation for all dynamic draft calculations per transect.

### **C3. Bar Check Comparisons**

Weekly bar checks were performed to confirm that the multibeam sonar was functioning properly and static draft was accurately documented. A Ross Laboratories Inc. Model 5150 lead target ball attached to the end of a wire cable and chain, marked at 3 meters, was used to bar check the multibeam on the *S/V Blake*. The 3-meter marks were checked periodically with a measuring tape.

The individual bar check devices were lowered to 3 meters depth below the water surface, a point above the natural bottom, where it could be clearly ensonified. The depth of the bar was compared to the depth of the bar reported by the sonars. Observations were recorded in a comparison log. Tabulated bar check comparisons may be found in the Weekly Bar Check logs included in Appendix II *Echosounder Reports*.

#### **C4. Heave, Roll and Pitch Corrections**

An Applanix POS/MV 320 V4 integrated dual frequency GPS and inertial reference system was used for the motion sensor for this survey. The POS/MV 320 is a 6-degree of freedom motion unit, with a stated accuracy of 0.05-meter or 5 percent for heave, 0.02 degrees for roll and pitch and heading. Real-time displays of the vessel motion accuracy were monitored throughout the survey with the MV-POSView controller program. If any of the vessel motion accuracy degraded to greater than 0.05 degrees root mean square (RMS), survey operations would be suspended until the inertial unit was able to regain the higher degree of accuracy. Manufacturer reported accuracies as published on the CARIS HIPS TPU website (<http://www.caris.com/tpu/>) were entered into the HVF and used for TPU computations for multibeam data acquired by the S/V *Blake*. Schematics of the vessel and sensor set-up for the S/V *Blake* are located in Appendix I *Vessel Reports*.

#### **C5. Patch Tests**

Multibeam patch tests were conducted for the S/V *Blake* to measure alignment offsets between the IMU sensor and the multibeam transducer and to determine time delays between the time-tagged sensor data. Multiple patch tests were performed throughout the project to verify the adequacy of the system biases. Patch tests were performed periodically throughout the project including at the beginning of the project, after any system replacement, and at the end of the project. Each patch test consisted of a series of lines run in a specific pattern, which were then used in pairs to analyze roll, pitch and heading alignment bias angles.

Roll alignment was determined by evaluating the reciprocal lines run over a flat bottom used for the latency test. The pitch tests consisted of set of reciprocal lines located on a steep slope or over a submerged feature. The yaw error was determined by running parallel lines over the same area as the pitch tests. All lines were run at approximately 3 knots to 6 knots. Patch tests were run in the local survey area. Selected pairs of lines were then analyzed in HIPS Calibration editor to measure the angular sensor bias values. Visual inspection of the data confirmed each adjustment.

All patch test data were processed using post processed Applanix POSpac MMS SBET positions.

Sonar offsets and alignment angles computed during patch tests were entered into the HVF. Sonar roll and pitch values were entered in HVF SVP1 field rather than the Swath1 field in order for the HIPS Sound Velocity tool to work correctly. Routine roll test lines were acquired to monitor the stability of the multibeam mount. Roll test results were included in the project vessel file.

Uncertainty estimates for the MRU alignment for gyro, pitch and roll were calculated by taking the average of the standard deviation on multiple iterations of patch test lines.

### **C6. Tide and Water Level Corrections**

The primary water level station used for the surveys H12737, H12738, H12739 and H12740 was Pilot Station East, SW Pass, Louisiana (8760922). H12847 was reduced using correctors from Dauphin Island, Alabama (8735180).

The Hydrographic Surveys Division (HSD) provided HIPS Zone Definition Files (ZDF) were used to apply zoned tides to the bathymetric data. The primary water level stations experienced no down time during periods of hydrographic survey up to the delivery of this report.

### **C7. Sound Velocity Correction**

During data acquisition, the MVP30-350 was deployed as needed to obtain an adequate number of sound velocity profiles to properly correct the multibeam data during data processing. Casts were taken at approximately 15-minute intervals. The location of casts along the survey track lines were varied to ensure adequate spatial coverage. If significant cast-to-cast variability was observed, the time between casts was decreased. All casts extended to at least 80 percent of water depth, with at least one deep cast (extending to 95 percent of depth) taken per day.

Checks were completed to verify pressure sensor and sound speed instrument performance. Corrections for the speed of sound through the water column were computed for each sensor. Sound speed profiles were imported and overlaid for comparison into an Excel file. All comparisons were well within survey specification. Sound speed check results are included in Separate II *Sound Speed Data Summary* of the Descriptive Reports.

The sound speed correction was applied to each line using the nearest in distance within time (one hour) option in the HIPS SVP correct routine. All casts were concatenated into a HIPS SVP file for each survey day. Time, position, depth, and sound speed for each profile were included in the HIPS file.

## **D. APPROVAL SHEET**

The letter of approval for this report follows on the next page.

DAVID EVANS  
AND ASSOCIATES INC.

## LETTER OF APPROVAL

### OPR-J377-KR2-15 DATA ACQUISITION AND PROCESSING REPORT

This report and the accompanying data are respectfully submitted.

Field operations contributing to the accomplishment of OPR-J377-KR2-15 were conducted under my direct supervision with frequent personal checks of progress and adequacy. This report and associated data have been closely reviewed and are considered complete and adequate as per the OPR-J377-KR2-15 *Statement of Work* (April 3, 2015), *Hydrographic Survey Project Instructions* and *Hydrographic Survey Project Instructions Mod 1*.
