Data Acquisition and Processing Report

NOAA S3003

OPR-L430-NRT6-14

Introduction

NOAA Navigation Response Team 6 (NRT6) is a mobile hydrographic survey team that operates in the southwestern region of the United States. The primary survey platform for NRT 6 is NOAA launch S3003, a 27-ft vessel built by SeaArk of Monticello, Arkansas, and delivered to NOAA in 2004. NRT 6 is staffed by three physical scientist technicians.

NRT 6's primary mission includes acquiring hydrographic survey data used to update NOS nautical charts. The team is also equipped to rapidly respond to navigational significant events such as natural disasters, vessel groundings and other incidents. NRT 6 responds to survey requests in the state of California and other geographic areas as necessary, made by harbor masters, pilots, and other stakeholders. Hydrographic surveys are performed using multibeam, side scan, and single beam sonars. Land-based surveying of shoreline features is performed using a Trimble GeoXH handheld GPS unit. A 32-ft trailer serves as a mobile field office, and is equipped with several data processing workstations.

This Data Acquisition and Processing Report (DAPR) details all Navigation Response Team 6 (NRT6) survey equipment and methods used to acquire and process survey data. Systems were selected for use during this project based on instructions from the Field Procedures Manual, Project Instructions, and Hydrographic Survey Specifications and Deliverables. Survey systems and methods used during this project were also chosen based on the water depth, sea and weather conditions, and the ability of the vessel to safely navigate the area.

A. Equipment

A.1 Survey Launch S3003

Survey Launch S3003 is a 27-ft SeaArk Commander, and is used to acquire side scan sonar data, multibeam echosounder data, singlebeam echosounder data, and sound velocity profiles. The 4.5 ton launch is 8 feet wide, has a static draft of 0.5 meters, and is powered by twin 150hp Honda outboards.

S3003 Vessel Information

Hull Number:	S3003
Builder:	SeaArk
Built:	2003
Length Overall:	33 ft.
Beam:	8 ft.
Draft:	1.6 ft.
Cruising Speed	28kts
Min/Max Survey Speed:	4-8kts.
Primary Echosounder:	Hull-mounted Simrad EM3002 MBES
Secondary Echosounder:	Hull-mounted ODOM Echotrac CV VBES
Imagery System	Towed Klein 3000 Side Scan Sonar system
Sound Velocity Profiler:	Sea-Bird SeaCat SBE 19+ CTD Profiler
Surface Sound Velocity Probe:	ODOM Digibar Pro

A.2 Sounding Equipment

A.2.1 Shallow Water Multibeam Sonar

S3003 uses a Kongsberg Simrad EM 3002 multibeam echosounder. The EM 3002 collects sounding and backscatter data at 300 kHz with 254 receive beams, which provide an optimal swath of 130°. The system is relatively “hands-off”, with range scale, power, gain, and other parameters automatically controlled by the sonar system. See Appendixes 3 and 4 for further information on the Simrad EM3002 setup.

This sonar is interfaced with the acquisition PC using the Simrad EM3002 SIS (Seafloor Information System) software application. SIS is used to acquire data from the EM3002 by creating .ALL files. Hypack Hysweep is still used to acquire .HSX files but these files are only being used for the purpose of real time matrix display.

Figure 1: Hull-mounted Simrad EM 3000 transducer.

The sonar head contains a flat-face transducer (Mills Cross configuration) and all transmitter and receiver elements encased in an acoustically transparent medium. The transmit beam is steerable to compensate for mounting angle and vessel pitch.

The processing unit performs the beam-forming, bottom detection and controls the sonar head with respect to gain, ping rate and transmit angle. It also contains the interfaces for all time-critical external sensors such as attitude data, position, and the 1 PPS (pulse per second) signal.

EM3002 SIS (Seafloor Information System) software operates on the Hypack computer and communicates via Ethernet connection, is used to control adjustable parameters. The controller software also transmits real time sound velocity measurements (from a Micro-X Oceanographer AML velocimeter mounted near the sonar head) to the processing unit for initial beamforming and steering.

The sonar head is hull mounted aft of the vessel cabin, centered on the keel line. The POS/MV IMU is centered above the sonar head. See the CARIS HVF for offset values.

A patch test was performed July 17, 2014. However, previous year's values proved more accurate after processing and comparison. 2013 patch test values continue to be used for 2014. Please see Appendix 8 for details of the patch test.

The sound velocity probe is mounted on the transom, between the outboard engines. The probe is housed in a PVC tube, which is then inserted into two brackets attached to the transom. This removable configuration allows for higher transit speeds between survey areas, while keeping the probe protected.

Figure 2: S3003 Digibar mount and protective PVC sheath.

A problem with this configuration is the tendency for air bubbles (turbulence) and debris, mostly floating eel grass, to become trapped in the PVC tube, leading to large errors in the sound velocity. This in turn causes the multibeam to incorrectly steer the incoming pings, seen as large “frowns” in the bathymetry. Data exhibiting this problem are noted, and data are re-acquired over the problem areas.

The problem of turbulence and eel grass has subsequently been mitigated for the most part by installing a 6 inch longer PVC tube so as to extend the velocity probe deeper below the water surface. Since this installation, we have seen fewer beam steering sound velocity errors. However, during times of calmer seas and/or cleaner water, free of floating eel grass we still prefer to use the shallower PVC tube as it is less likely to suffer debris damage and interference from the engines in the “up” position during transit between survey areas.

A.2.2 Side Scan Sonar

NRT 6 operates an Edgetech 4125 side scan sonar system, used for the detection of submerged wrecks and obstructions. Two dual simultaneous frequency sets are available for the 4125 depending on the application. The 400/900 kHz set is the perfect tool for shallow water survey applications, providing an ideal combination of range and resolution. The 600/1600 kHz set is ideally suited for customers that require ultra high resolution imagery in order to detect very small targets. Typical surveys see the SSS used in high frequency mode, with range scales between 50 and 100 meters, as specified in the HSSD section 6.2.4. The system consists of a towfish, deployed from a rotating boom on the aft deck (see figure 7). The towfish is connected to a slip ring attached to an electric

winch, which is connected to the Transceiver and Processing Unit (TPU). The TPU is networked to a workstation that allows the user to control various parameters, view SSS imagery and record sonar files. Measurements to the towpoint can be found in the survey offset report, Appendix 1, and a calibration report for the system is found in Appendix 9.

Figure 3: S3003 Edgetech 4125 SSS installation.

All SSS data collection is controlled using Discover II software operating in a Microsoft Windows 7 environment on the Acquisition Workstation. Control signals are sent to the towfish and data is received from the towfish via the TPU. Data is recorded digitally and stored on the Acquisition Workstation in Edgetech format.

Side scan sonar lines are spaced according to the range scale appropriate for the water depth. Lines are planned with a minimum of 25 meters of overlap with adjacent swaths. Vessel speed is adjusted to ensure that an object one meter square in size would be detected and clearly imaged across the sonar swath. Typical SSS collection speed is five knots. Confidence checks are performed by observing operation of the SSS along pier faces, buoy blocks, and in areas with known targets.

High frequency of 600/1600 kHz set is utilized as the primary frequency for data collection, with low frequency observed, but not logged. The maximum range scale used is 100 meters, with operation on the 50 to 75 meter range scales more typical. Fish height is kept at eight to twenty percent of the range scale, except in very shallow areas (< 6 meters).

S3003 is equipped with a Dynapar cable counter used to measure the length of towfish cable deployed by counting revolutions of the towing block on the J-frame. The length of

cable deployed is computed automatically and output directly to the Acquisition Workstation where it is used by the Discover II software.

A.2.3 Vertical Beam Echosounder

S3003 is equipped with an Odom Echotrac CV Vertical Beam Echosounder (VBES). The Odom CV is a single-beam echo sounder, operating at 208 kHz with an 8° beam. Unlike previous Odom Echotrac models, the CV has no display or paper record on the actual processor; rather, sounding data is displayed in Hypack. VBES data are collected infrequently, as both multibeam and side scan sonar may be operated simultaneously. This system is used infrequently, as most projects now require the collection of SWMB data.

A.2.4 Lead line

NRT6 uses a lead line for echosounder calibration tests. It is a non-stretching synthetic line, marked every half-meter, with a lead weight attached at the bottom. See Appendix 7.

A.3 Positioning Equipment

A.3.1 POS MV Positioning and Orientation System

S3003 is equipped with an Applanix Model 320 Version 5 POS/MV, interfaced with controller software installed on the Hypack computer. A Trimble SPS361 provides differential correctors to the POS/MV, and is also interfaced on the Hypack computer via Trimble Seacast software. The Inertial Measurement Unit (IMU) is located in a hatch aft of the cabin, directly over the multibeam transducer. The antennae are located on the top of the cabin, on mounts that raise them off of the deck. The antenna for the Trimble receiver is located on the top of the mast.

A.3.2 Trimble SPS361

Survey launch S3003 is equipped with a Trimble SPS361 DGPS beacon receiver.

The Trimble SPS361 is a dual-frequency GPS Heading receiver available with or without an internal MSK Beacon receiver. The SPS361 receiver is capable of DGPS positioning accuracies using any of the following differential correction sources:

- Satellite-Based Augmentation Systems (SBAS) corrections (WAAS/EGNOS/MSAS)
- DGPS RTCM corrections from the internal MSK Beacon receiver
- DGPS RTCM corrections from an external source
- RTK corrections from an external source (solution is limited to DGPS precision)
- OmniSTAR VBS correction service from an internal demodulator
- OmniSTAR VBS correction service from an external source

A.3.3 Trimble GeoXH Handheld GPS

The GeoXH is used to position AtoNs and assist with shoreline. Fixed Aids to Navigation (AtoNs) are occupied for a minute or longer, which allows for a horizontal precision of 0.1 meter or less after post processing.

NRT6 uses the standard data dictionary given in Appendix 5 of the Field Procedures Manual.

NRT6 processes rover data collected on the GeoXH using Pathfinder software. Data are post-processed using local CORS stations. Typical processing uses multiple CORS sites, as there are numerous sites in NRT6's operating area.

For AtoNs, the processed file is then exported as a SHP file, and formatted for submission to MCD, as outlined in Appendix 5 of the Field Procedures Manual.

A.4 Software

Basic descriptions of the various software used for acquisition, processing, and other tasks are listed below. For further information, including details about software versions and other information, please see the appendix 5, Hydrographic Systems Inventory.

A.4.1 Acquisition Software

A.4.1.1 Hypack

Coastal Oceanographic's Hypack Max is used for vessel navigation and line tracking during data acquisition. NRT6 used HYPACK 2014 for this survey.

Hypack Max's Survey program is used to log SBES data and is used in conjunction with Hypack Max's Hysweep Survey program to log MBES data. SBES and MBES data are logged in the Hypack "raw" format, with SBES data using the day number as an extension and MBES data using the .hsx extension. Both are ASCII text files.

A.4.1.2 Discover II

Discover II version 2012 is used to monitor and log all side scan sonar data from the Edgetech 4125 sonar. Data is recorded in .jsf format.

A.4.2 Processing Software

A.4.2.1 CARIS HIPS/SIPS

NRT6 uses CARIS HIPS/SIPS 8.1, updated with the most current hotfixes, to process all sonar data. See Appendixes 10 and 11 of the [HSRR](#) for a detailed discussion of the current CARIS HVF file.

A.4.2.2 MapInfo

Mapinfo 10.5 is used on all processing computers for project planning, and creating survey products. HydroMI, a NOAA in-house software application, is used with MapInfo to convert planned lines for use with Hypack, create chartlets, and perform a number of other survey-related tasks.

A.4.2.3 Pydro

The latest version of Pydro is installed on the three main processing workstations. Pydro is used to organize survey feature data and bathymetry, to generate reports, and for a number of other survey-related tasks.

A.4.2.4 CARIS Bathy DataBase

The latest version of CARIS DataBase is installed on the three main processing workstations. Pydro is used to organize survey feature data and bathymetry, to generate reports, and for a number of other survey-related tasks.

A.4.3 Other Software

Velocipy is used to process CTD casts into CARIS .SVP files, used to correct the sound velocity profile in CARIS.

B. Data Processing and Quality Control

B.1 Shallow-Water Multibeam Data

Shallow-water multibeam (SWMB) data were monitored in real-time using the 2-D and 3-D data display windows in Hypack Hysweep, and the Simrad controller window. As the Simrad EM3002 is a relatively “hands-off” system, few parameters are adjustable by the sonar operator. Ping rate, range scale, power, and gain are all automatically adjusted by the Simrad system. In the Runtime Parameters menu, under Sounder Main, the user is able to set a maximum ping rate, and a minimum and maximum depth.

Simrad SIS .ALL files were converted to CARIS HDCS files following acquisition. Tide, sound velocity (SVP), vessel offset, dynamic draft, and True Heave correctors were then applied and merged with depth, position and attitude data to compute the corrected depth and position of each sounding. The Total Propagated Uncertainty (TPU) was then computed for each sounding, using the error values included in the CARIS HIPS Vessel File (HVF). TPU values are used to create a Bathymetry Associated with Statistical Error (BASE) surface, a grid comprised of nodes that contain bathymetric and uncertainty information. NRT6 uses the Combined Uncertainty and Bathymetric Estimator (CUBE) algorithm to create BASE surfaces from SWMB data. The CUBE algorithm creates a BASE surface grid by first creating depth hypotheses at each grid node, and then using density, locale, or a combination of the two to choose the best hypothesis. NRT6 used the parameters (and the associated XML file) outlined in Hydrographic Technical Directive 2009-2 for the surfaces generated in this survey. Specifically, NRT6 used the NOAA_1m and NOAA_0.5m CUBE parameters. Please see the HVF Review, located in the HSRR, for updated information on the TPU values used in during this project.

The BASE surface is then used to conduct area-based editing in CARIS subset mode, which allows the processor to focus on specific areas with higher uncertainty values and also a high number of CUBE hypotheses. In addition to area-based editing, subset tiles were also used to systematically review the entire project area in subset mode. Both of these review methods include removing fliers and or noise in the water column, as well as picking the least depth on significant contacts. Filtering was also used to assist in cleaning noise and fliers. NRT6 used the IHO Order 1 filter in CARIS for this project.

B.2. Side Scan Sonar Data

Side Scan Sonar (SSS) data were collected and monitored with Discover II software, version 2012. Files were saved in .jsf format. Range scale, gain, and towfish height were all adjusted to ensure the collection of quality data, and that the imagery and towfish height met the requirements of the HSSD. Sonar imagery quality checks were performed on objects located within the survey area.

.jsf are converted to CARIS SIPS files, and reviewed for significant contacts using the Side Scan Editor. Contacts are then exported into Pydro, where they are then examined and categorized based on significance. Significant contacts are noted, and are later developed using SWMB. Mosaics of the data are created to ensure complete coverage of the survey area.

All SSS data were examined and re-acquired if motion artifacts, boat wakes, or refraction prevented the identification of targets while examining side scan data.

B.3. Composite Source File

A composite source file (CSF) was included with this project. The CSF items were imported into Caris Bathy DataBASE and clipped so that all objects outside the sheet extents were excluded. The items were then filtered in Caris Bathy DataBASE by object class to create a manageable workspace. Mandatory object classes were brought into Pydro and items that were deemed too shallow or dangerous to investigate were not marked “Investigate”. The remaining items were selected to investigate, and Hypack targets were exported. Boat sheets with images of the CSF items located on the chart were created, and used for notes on the items while surveying. These sheets were scanned and are located under Acquisition Logs in the CSF folder.

In Caris Bathy DataBASE, all CSF items were marked with the keyword “CSF”, and a separate “CSF Items” tab was created. The CSF items were then correlated to SSS and MB features. Items that were not found were classified “Chart-Delete”. Items that were present, but differed from the CSF description were classified secondary to sonar features, and marked “Chart-Modify”. Items that were investigated and found, but did not differ from the CSF items were classified “Chart-None”. All S-57 attributes were assigned for each CSF item investigated. If the item was not found or investigated, the S-57 information from the original CSF was retained. CSF items on the chart that were picked to be modified or deleted will also be included in the Survey Feature Report located in Appendix II.

The Navigation Response Branch is in the process of streamlining the CSF process to guarantee that future submissions include all pertinent CSF items while taking out redundancies and extra work that clutters the survey area. The new assigned feature files (AFF) will supersede the original CSFs and are currently being compiled for the San Francisco Bay area.

C. Corrections to Echo Soundings

C.1. Sound Velocity

NRT 6 collects conductivity, temperature, and density (CTD) data using an SBE 19+ to determine sound speed profiles, which are used to correct multibeam sonar data. The SBE19 generates a raw hexadecimal file (*.hex), which is used by Velocipy, a NOAA in-house program that converts .hex files to files used to correct multibeam data. Velocipy is discussed in the Data Processing Software section, 3.3. Please see Appendix 6 for the latest calibration report.

An AML Oceanographer Micro-X is used for continuous sound velocity measurements at the face of the multibeam transducer to correct for the geometry of a flat transducer array. The AML Oceanographer Micro-X is mounted on the transom, housed inside a PVC tube that allows a free flow of water over the sensor. Sound speed data is sent from the AML Oceanographer Micro-X to the Hypack acquisition PC via a serial cable. Please see Appendix 6 for the latest calibration report.

Sound velocity profiles were acquired with the SeaBird Electronic SeaCat SBE19Plus Conductivity, Temperature, and Depth (CTD) profiler (see HSRR Appendixes 5 and 6 for serial numbers and calibration dates). Raw CTD data were processed using the program Velocipy.

An Odom Digibar Pro sound velocimeter, mounted on the transom, measured the speed of sound near the face of the transducer. The Simrad EM3002 has a flat-faced transducer, necessitating corrections to the returning wave front based on the speed of sound.

C.2. Vessel Offsets and Dynamic Draft Corrections

Measurements to verify the vessel offsets currently used by NRT6 were taken by a survey team from the National Geodetic Survey in March 2009. New offset measurements from the reference point to the multibeam transducer and IMU were taken following the retrofitting of the multibeam transducer. Both were relocated to points aft of the cabin.

Static and dynamic offsets, unless otherwise noted, are entered into CARIS HIPS Vessel Files (HVF). A separate HVF is used for the multibeam and singlebeam echosounders, and for 100% and 200% sidescan. Uncertainty values for all offset measurements are also recorded in the HVF, in the Total Propagated Uncertainty section.

Angular offsets and navigation timing errors of the multibeam system were determined using a patch test. A series of calibration lines are run and processed using the CARIS Calibration mode. The patch test report may be found in the 2014 HSRR, Appendix 8.

Static and dynamic offsets (settlement and squat values), angular offsets, and navigation timing errors are entered into the CARIS HIPS Vessel File (HVF), which is used to correct CARIS HDCS data.

Vessel Static Offsets

In March 2009, personnel from the National Geodetic Survey measured the offsets of all sensors aboard launch S3003, following the re-installation of the multibeam transducer to a hull-mounted configuration. NGS values for the multibeam transducer and IMU agreed with the initial post-installation measurements (measured by NRT6 personnel) to within a centimeter in all dimensions. Please see Appendix 1 for the NGS Offset Measurement Report.

NRT6 uses a reference point that is located near the vessel center of motion, from which all offsets are measured. The POS controller sets the center of Navigation and Attitude at the reference point on the IMU. Sensor offsets from the reference point are then entered into the CARIS HVF. Please see Appendix 11 for the HVF Report.

POS MV Phase Center Offset Adjustment

The phase center for the POS MV was determined to be 1 cm below the top of the antenna. The antenna was measured from its base to the top, and a value of 4.6 cm (see the engineering drawing below, Figure 1) was subtracted from the total measured value to obtain the offset from the top of the antenna to the phase center. The measured vertical offset value from the NGS survey, from the IMU to the port GPS antenna is -2.587 (in POS coordinate system with Z-axis positive downward). Corrected for the phase center and for the new V5 IMU, this value is now -2.607. This correction only affects the offset from the Primary GPS antenna to the IMU, which is entered in the POS Controller software. See Appendix 4 for a screen grab of the updated offset values in the POS MV Lever Arms & Mounting Angles window.

POS MV V4 Installation and Operation Guide

Drawings

Figure 77: GPS Antenna Footprint

Figure 4: Engineering drawing from POS MV manual, Appendix E.

Vessel Dynamic Offsets

Static Draft

The static draft of the vessel was measured on March 30th, 2009. This measurement was made separately from the NGS survey, as the waterline was not clearly marked at the time of that survey. The vessel was again leveled, using the IMU plane of reference, and levels and t-squares were used for measurements. The resulting waterline value is -.024 m from the reference point, and has changed .026 m. The waterline was chosen to be the line of marine growth on the vessel hull. The main source of uncertainty in this measurement was choosing the waterline. The thickness of the marine growth line was approximately 2 cm, which is larger than the assumed uncertainty for the actual measurement, and thereby used as the Draft TPU value in the HVF.

Dynamic Draft

A dynamic draft test was conducted in October 2012. This test was performed using the Ellipsoid Referenced Dynamic Draft Method (ERDDM) or PPK method outlined in section 1.4.2.1.2.1 of the Field Procedures Manual. The results were satisfactory, and were entered into the Draft section of the CARIS HVF. Please see Appendix 2 for a report detailing the process of calculating the dynamic draft values.

C.3 Heave, Pitch, Roll, Heading, and Timing

S3003 is equipped with an Applanix POS/MV V 5, interfaced with controller software installed on the Hypack computer. A Trimble SPS361 provides differential correctors to the POS/MV, and is also directly interfaced on the Hypack computer. The Inertial Measurement Unit (IMU) is located directly above the multibeam transducer, inside a hatch that provides access to the IMU and transducer. The antennae are located on the top of the cabin, on mounts that raise them off of the deck. The antenna for the Trimble receiver is located on the top of the mast.

A GAMS calibration was performed following the re-positioning of the IMU to a location directly above the multibeam transducer.

Figure 5: View of top of house on Launch S3003. Center GPS antenna is used by Trimble SPS361 receiver, and two lower antennae are used by the POS/MV V5.

Figure 6: IMU mounted in hatch directly above the multibeam transducer.

The POS/MV 320 provided attitude data to SIS, which stored the data in the ALL multibeam file. Attitude data quality is monitored while surveying by monitoring the POS Controller window, which is installed on the Hypack workstation. Alarms are triggered when accuracy values fall below user-determined values.

As discussed in the previous section, navigation timing error is determined using the patch test, and applied to data using the CARIS HVF.

C.4 Water Level Correctors

Soundings were reduced to Mean Lower-Low Water (MLLW) using preliminary tides, taken from stations 9414750, Alameda, CA, 9414290, San Francisco, CA and 9414863 Richmond, CA. The Zone Definition File for this project was L430NRT62014CORP.zdf. The .zdf file breaks the survey area into polygons that take into account the magnitude and time differences from a primary tide gauge. Once available, the verified tide data is applied before submitting hydrographic survey data.

D. Approval

As Chief of Party, I have ensured that standard field surveying and processing procedures were used during this project in accordance with the Field Procedures Manual, and the NOS Hydrographic Surveys Specifications and Deliverables Manual, as updated for 2014.

I acknowledge that all of the information contained in this report is complete and accurate to the best of my knowledge.

NOAA SURVEY VESSEL S3003 POS MV COMPONENTS SPATIAL RELATIONSHIP SURVEY

PURPOSE

The primary purpose of the survey was to precisely determine the spatial relationship between various hydrographic surveying sensors, and the components of a POS MV navigation system aboard the NOAA survey vessel S3003.

PROJECT DETAILS

This survey was conducted in Richmond, California on the 10th of March, 2009. The weather was cool and clear in the morning, with warm and clear conditions in the afternoon. For this survey, the vessel was on a trailer stabilized by the trailer tongue jack and two hydraulic bottle jacks. The vessel was leveled relative to the IMU.

INSTRUMENTATION

A Leica (Wild) TC300 precision total station was used to make all measurements.
Technical Data:

Standard Deviation	
Horizontal angle	0.5 seconds
Vertical angle	0.5 seconds
Distance measurement	1mm + 1ppm

Standard precision prisms were used as sighting targets. Prisms were configured to have a zero mm offset.

Kendall Fancher	NOAA/NOS/NGS/GSD/I&M BRANCH (540) 373-1243
Dennis Lokken	NOAA/NOS/NGS/GSD/I&M BRANCH (540) 373-1243

**NOAA SURVEY VESSEL S3003
POS MV COMPONENTS SPATIAL RELATIONSHIP SURVEY****DEFINITION OF THE REFERENCE FRAME**

To conduct this survey a local coordinate reference frame was established where the Northing (Y) axis runs along the centerline of the boat and is positive from the primary reference point towards the bow of the boat. The Easting (X) axis is perpendicular to the centerline of the boat and is positive from the primary reference point towards the right, when looking at the boat from the stern. The Up (Z) axis is positive in an upward direction from the primary reference point.

SURVEY METHODOLOGY

Three temporary control points, (1, 2, 3), were established around the vessel such that every point to be positioned on the launch could be observed from at least two separate locations.

Coordinates of 100.000N, 100.000E, and 100.000U were assumed for control point 1. A distance and height difference were measured between control points 1 and 2. These values were used to determine the coordinates for control point 2 of 120.469N, 100.000E, and 99.984U.

Control point 1 was occupied and control point 2 was observed for a backsight. After initialization, control point 3 and all points to be observed on the launch were observed in both direct and reverse.

Control point 2 was occupied and control point 1 was observed for a backsight. After initialization, control point 3 and all points to be observed on the launch, except for the Single Beam transducer (SB), were observed in both direct and reverse.

Control point 3 was occupied and control point 1 was observed for a backsight. After initialization, control point 2 and SB were observed in both direct and reverse.

Inverses were computed between the two positions determined for all points surveyed to evaluate the accuracy of the survey.

The reference frame was rotated using Centerline Stern (CLS) as the point of rotation. A zero degree azimuth was used during the rotation from CLS to Centerline Bow (CLB). The reference frame was then translated to relocate the origin of the reference frame to Primary Centerline reference point (CL0).

**NOAA SURVEY VESSEL S3003
POS MV COMPONENTS SPATIAL RELATIONSHIP SURVEY**

Inverse Results

Inverses were computed between the two occupations of each positioned point. The results of these inverses are:

ID	Horizontal Dist.(m)	Elevation Diff(m)
2	0.0005	0.0006
3	0.0003	-0.0003
SB	0.0004	0.0004
MB	0.0005	0.0002
GPSP	0.0001	0.0000

DISCUSSION

The positions given for the POS GPS antennas (Zephyr p/n 39105-00) are to the top center of the antenna. To correct the Z value provided in this report for each antenna to the electronic phase center, I recommend the following steps be taken;

- 1) Determine the physical height of the GPS antenna. This information is probably located on the antenna or with equipment documentation.
- 2) Investigate to find the electronic phase center offset of the antenna. This information is probably located on the antenna or with equipment documentation. This value may also be available at the NGS website for antenna modeling.
- 3) Subtract the total height of the antenna from the Z value for each antenna. This will give you a Z value for the antenna ARP (antenna reference point)
- 4) Then add to this value the electronic phase center offset value appropriate for the antenna model.

An offset value of -0.25m has been applied to the Side Scan Sonar reference point (SSS) to translate the Z value from the observed reference point to an imaginary point atop the cable in the block used for this sensor in the deployed position.

**NOAA SURVEY VESSEL S3003
POS MV COMPONENTS SPATIAL RELATIONSHIP SURVEY****Station Listing**

- CL0- CENTERLINE PRIMARY REFERENCE POINT
An existing punch mark set in top of the metal housing for a hatch, located inside the cab and flush with the floor surface. Stamped “CL0”.
- CLB- CENTERLINE REFERENCE POINT BOW
A punch mark set in top center of a cleat, located near the bow of the vessel. Stamped “CLB”.
- CLS- CENTERLINE REFERENCE POINT STERN
A punch mark set in top of the center rib in the generator hold. Stamped “CLS”.
- CLT- CENTERLINE REFERENCE POINT TRANSOM
A punch mark set in top center of the transom. No stamping.
- MB- MULTIBEAM TRANSDUCER REFERENCE POINT
The center of the bottom of the Multi Beam Transducer.
- SB- SINGLE BEAM TRANSDUCER REFERENCE POINT
The center of the bottom of the Single Beam Transducer.
- SSS- SIDE SCAN SONAR REFERENCE POINT
An unmarked point located at the center of the bottom of the swing arm at a point directly below a drill hole which is used to suspend the Side Scan Sonar cable tackle.
- IMU- IMU REFERENCE TARGET
Center of a target affixed to the top of the IMU housing.
- GPSP- POS GPS ANTENNA REFERENCE POINT
The top center of the port side GPS antenna for the POS system.
- GPSS- POS GPS ANTENNA REFERENCE POINT
The top center of the starboard side GPS antenna for the POS system.

Appendix 2: Dynamic Draft Report

Settlement and Squat Report Navigation Response Team 6 Launch S3003

Procedures

Acquisition

Data for the test were acquired on March 27th 2013, in the vicinity of South Hampton Shoal Channel in San Francisco Bay. This was a flat, featureless area located within a reasonable distance to the vessel's current projects.

The test consisted of logging POSPac data while running a line in opposite directions. The vessel's RPMs were increased from 800 RPM to 2200 RPM by 200 RPM increments in two minute intervals. A 5 minute dead-in-the-water rest period was performed at the beginning, middle and end of the test.

Processing

Following data collection, the POSPac data was processed in Applanix POSPac MMS 5.4 SP2. A SmartBase region was created using the GPS base stations BRIB, P262, P224, SVIN, UCSF, and P181 with P181 being the control station.

Figure 1. SmartBase Region for NRT 6 ERDDM

The produced SBET (Smoothed Best Estimate of Trajectory) was then processed in Pydro 12.9 (r3952) with the ProcSBETDynamicDraft.py macro using the tide correction

functionality and a 4th order polynomial curve. A ZDF from the OPR-L430-NRT6-12 project was used to determine the zone values and tide gauge data to download.

Results

The results from Figure 2 generated by the macro were entered into the Draft section of the CARIS HVF, NRT6_S3003_EM3002_2013.hvf on April 1st with time stamp 2013-091, 00:00. The uncertainty from this test was taken from 1 STD value of approximately 0.03 found in Figure 2 and entered in the HVF under the TPU StdDev entry Delta Draft. The results of this test compare favorably to previous year’s results.

Figure 2. Plots generated by the Pydro macro used to populate the CARIS HVF

Installation Sensors and Settings

COM2 receives attitude data from the POS MV.
 COM3 is used to receive navigation and timing from the POS MV.

The screenshot displays the SIS (Sonar Installation Software) interface. The main window is titled "Installation and Test" and contains several tabs: "Settings", "Locations", "Angular Offsets", and "ROV. Specific". The "Angular Offsets" tab is active, showing a table for "Offset angles (deg.)".

	Roll	Pitch	Heading
Sonar head 1:	0.00	0.00	0.00
Sonar head 2:	0.00	0.00	0.00
Attitude 1, COM2/JDP5:	0.00	0.00	0.000
Attitude 2, COM3/JDP6:	0.00	0.00	0.00
Stand-alone Heading:			0.00

On the right side of the interface, there is a "Numerical display" panel showing various system parameters and their values. The "Soundspeed" parameter is highlighted in red and shows a value of 1517.60. Other parameters include SV Profile (0.00), SV Used (-9999.0), SV sensor (1.21), Pitch (-1.18), Roll (0.00), Heave (0.10), Speed kn (2014 07 22), Ext. Date (21:53:31), Ext. Time (2014 07 22), PU Date (21:53:30), PU Time (1), PU - ZDA (6), PU - POS (0.00), Depth (Normal), Mode (HD EQDST), Beam sp. (0/0), Beams (0/0), Coverage (0/0), Port/Stb. (N 37.91427 North DD.C, W 122.35496 East DD.D), Heading (222.00), Ping Hz (0.00), HDOP (1.00), Qfactor (2), PPS (On), Height (0.00), No. sat. (8), TX pow. (0.00), Temp. prot. (-99999.0), Tide (0.00), Geo. und. (0.00), Geo. vref. (0.00), and RTCM Log. (---).

At the bottom of the interface, a status bar displays the following information: "ence between sound speed from probe and profile (131)", "Beam sp.: HD EQDST", "Soundspeed: 1517.60", "Across: 0.00", "Depth: 0.00", and "Mode: Normal".

Certified By:

Robert Haydock
President, AML Oceanographic

AML Oceanographic certifies that the asset described above has been calibrated or recalibrated with equipment referenced to traceable standards. Please note that Xchange™ sensor-heads may be installed on assets other than the one listed above; this calibration certificate will still be valid when used on other such assets. If this instrument or sensor has been recalibrated, please be sure to update your records. Please also ensure that you update the instrument's coefficient values in any post-processing software that you use, if necessary. Older generation instruments may require configuration files, which are available for download at our Customer Centre at www.AMLoceanographic.com/support

Conductivity Calibration Report

Customer:	NOAA/NRT6		
Job Number:	80916	Date of Report:	8/19/2014
Model Number	SBE 19Plus	Serial Number:	19P37217-4676

Conductivity sensors are normally calibrated 'as received', without cleaning or adjustments, allowing a determination of sensor drift. If the calibration identifies a problem or indicates cell cleaning is necessary, then a second calibration is performed after work is completed. The 'as received' calibration is not performed if the sensor is damaged or non-functional, or by customer request.

An 'as received' calibration certificate is provided, listing the coefficients used to convert sensor frequency to conductivity. Users must choose whether the 'as received' calibration or the previous calibration better represents the sensor condition during deployment. In SEASOFT enter the chosen coefficients. The coefficient 'slope' allows small corrections for drift between calibrations (consult the SEASOFT manual). Calibration coefficients obtained after a repair or cleaning apply only to subsequent data.

'AS RECEIVED CALIBRATION' Performed Not Performed
 Date: Drift since last cal: PSU/month*
 Comments:

'CALIBRATION AFTER CLEANING & REPLATINIZING' Performed Not Performed
 Date: Drift since Last cal: PSU/month*
 Comments:

**Measured at 3.0 S/m
 Cell cleaning and electrode replatinizing tend to 'reset' the conductivity sensor to its original condition. Lack of drift in post-cleaning-calibration indicates geometric stability of the cell and electrical stability of the sensor circuit.*

NARRATIVE

This patch test was conducted for the 2014 HSRR. NRT6 found the patch numbers for 2014 unfavorable after processed data was compared to 2013 results. Therefore, 2013 patch values will be used.

Appendix 9: Side Scan Calibration Report

Side Scan Calibration Report
Navigation Response Team 6

NRT6 Edgetech 4125 failed initial calibration test conducted 7/15/2014. NRB are currently working on a solution. As a result, NRT6 Edgetech 4125 will be used for emergency response operations only.

Appendix 10: CARIS HVF TPU Review

NRT6 CARIS HVF TPU ReviewCurrent as of August 27th, 2014

The purpose of this document is to thoroughly examine the Total Propagated Uncertainty (TPU) values used by NRT6 in its HIPS Vessel File for the Simrad EM3002 multibeam echosounder. TPU is used during the creation of Combined Uncertainty and Bathymetry Estimate surfaces. The current values in the Offsets and StdDev sections are listed and detailed below. These values supersede those detailed in the 2011 HSRR.

Please note that NRT6 uses a reference point that is not the IMU, but located close to the center of the vessel.

NRT6_S3003_EM3002**Offsets**

MRU to Trans X (m) -0.001 m

This value is derived from the 2008 NGS surveyed performed on S3003. It is the measurement from the IMU to the MB transducer.

MRU to Trans Y (m) .006 m

This value is derived from the 2008 NGS surveyed performed on S3003.

MRU to Trans Z (m) 0.386 m

This value is derived from the 2008 NGS surveyed performed on S3003 and was re-measured in 2014 when a new and smaller IMU was installed.

Nav to Trans X (m) 0.754 m

This value is derived from the 2008 NGS surveyed performed on S3003.

Nav to Trans Y (m) -3.149 m

This value is derived from the 2008 NGS surveyed performed on S3003.

Nav to Trans Z (m) 2.993 m

This value is derived from the 2008 NGS surveyed performed on S3003. The original measurement from NGS did not include a correction for the phase center, but measured to the top of the antenna. Engineering drawings place the phase center .053 m above the base of the antenna. The measured height of the antenna from base to top is .063 m, placing the phase center 0.01 m below the measured value of the NGS survey.

The measured values (from the reference point) are 2.520 (RP to antennae) + .483 (RP to MB Transducer) = 3.003 m. The absolute values of these two offsets are used, since we are measuring the total distance from above the RP, to the transducer below the RP. Z-axis values from the NGS survey were positive in the up direction. We subtract 0.01 m from the measured value, since the phase center reduces the total distance. The final offset value is 2.993 m. This value will also be updated in the POS controller software offset section.

Trans Roll (deg): 0.000 deg

StdDev

Motion Gyro (deg): 0.020 deg

This value is given as the manufacturer's recommended value for the Applanix POS/MV 320, as specified in HSTD 2007-10.

Heave % Amp 5.000%

This value is given as the manufacturer's recommended value for the Applanix POS/MV 320, as specified in HSTD 2007-10.

Heave (m) 0.050 m

This value is given as the manufacturer's recommended value for the Applanix POS/MV 320, as specified in HSTD 2007-10.

Roll (deg) 0.020 m

This value is given as the manufacturer's recommended value for the Applanix POS/MV 320, as specified in HSTD 2007-10.

Pitch (deg) .020 m

This value is given as the manufacturer's recommended value for the Applanix POS/MV 320, as specified in HSTD 2007-10.

Position Nav (m) 1.000 m

This value is given as the manufacturer's recommended value for the Applanix POS/MV 320, as specified in HSTD 2007-10.

This value is subject to change based on the quality of the differential signal during acquisition. The NRT6 working area for 2011-2012 is the central California coast from Monterey to San

Francisco Bay, and should have good coverage. HSTD 2007-10 recommends values from 0.5m to 2m. 1m is the default value, and is used for NRT6.

Timing Trans (s) 0.005s

No default is given for this value in HSTD 2007-10, but uncertainty values for attitude timing, using an Ethernet setup, are listed as .005 seconds. This value has been used, as the connection between the Simrad EM3000 and the host PC is a crossover Ethernet connection.

Nav Timing (s) 0.005s

This is the recommended value for installations using Ethernet connections to send attitude data from the POS/MV to the host PC.

Gyro Timing (s) 0.005s

This is the recommended value for installations using Ethernet connections to send attitude data from the POS/MV to the host PC.

Heave Timing (s) 0.005s

This is the recommended value for installations using Ethernet connections to send attitude data from the POS/MV to the host PC.

Pitch Timing (s) 0.005s

This is the recommended value for installations using Ethernet connections to send attitude data from the POS/MV to the host PC.

Roll Timing (s) 0.005s

This is the recommended value for installations using Ethernet connections to send attitude data from the POS/MV to the host PC.

Offset X (m) 0.003m

A full survey of the vessel sensors was performed by members of NOAA's National Geodetic Survey. A level was used to "shoot" points around the vessel, and, to estimate error, the points were shot in reverse. The difference was then calculated between the forward and reverse values. The average difference in the horizontal measurements was 0.003m.

Offset Y (m) 0.003m

A full survey of the vessel sensors was performed by members of NOAA's National Geodetic Survey. A level was used to "shoot" points around the vessel, and, to estimate error, the points

were shot in reverse. The difference was then calculated between the forward and reverse values. The average difference in the horizontal measurements was 0.003m.

Offset Z (m) 0.001m

The average difference in vertical measurement in the forward and reverse directions was less than 0.001m, however the instrument precision was given as 0.001m, so that value is used.

Vessel Speed (m/s) 0.503

Dependent on the average current in the area. Most NRT6 surveys during 2014 will take place in San Francisco Bay, which has relatively swift currents. This may result in large values for this uncertainty.

Loading (m) 0.011 m

Survey personnel marked the vessel waterline with a nearly empty fuel tank, and then filled the fuel tank. The waterline was then remarked, and the vessel was hauled out of the water. The difference between the average difference between the marks (marks were placed on the port and starboard sides) was 0.011 m.

Draft (m) 0.02 m

Measurement to the waterline was not performed by NGS during their survey, but during an offset survey performed by NRT6 personnel in 2009. The methods used during that survey resulted in values with 1cm of the NGS values. However, the measurement to the waterline was performed by taking a measurement to the “scum” line while the vessel was on the trailer. This line is not distinct and has a thickness of about .02m, This value will be used as the draft uncertainty.

Delta Draft (m) 0.03 m

Taken from the 2013 Settlement and Squat test, this uncertainty value was taken from 1 STD value of approximately 0.03 found in Figure 2 and entered in the HVF under the TPU StdDev entry Delta Draft.

MRU Align StdDev gyro 0.250 deg

Standard deviation for multiple yaw patch test values given a standard deviation of 0.25 degree.

MRU Align StdDev Roll/Pitch 0.1 deg

Standard deviation for multiple pitch/roll patch test values given a standard deviation of 0.1 degree.
