

Predicted tides for reduction of soundings on the field sheet are based on Seldovia, Alaska reference station. Final tide reducers for the smooth sheet are derived from the single gage in Wide Bay operated by the field party. Tides for JD 233 (1982) were inferred due to tide gage malfunction. The inferred values were estimated to be accurate to within  $\pm 0.5$  feet. (See attached memorandum, N/QMS123, dated March 1, 1984)
